CRSNG**

# Outline of Results Obtained in The Past Year

**1)**

**New results on the assessment of whether/how changes in extreme floods are occurring over time across Canada (D. Burn and collaborators)**

**This involves identification of regional or local increasing or decreasing trends and quantification of rates of change during the period of record**

# Research Results (continued)

2)

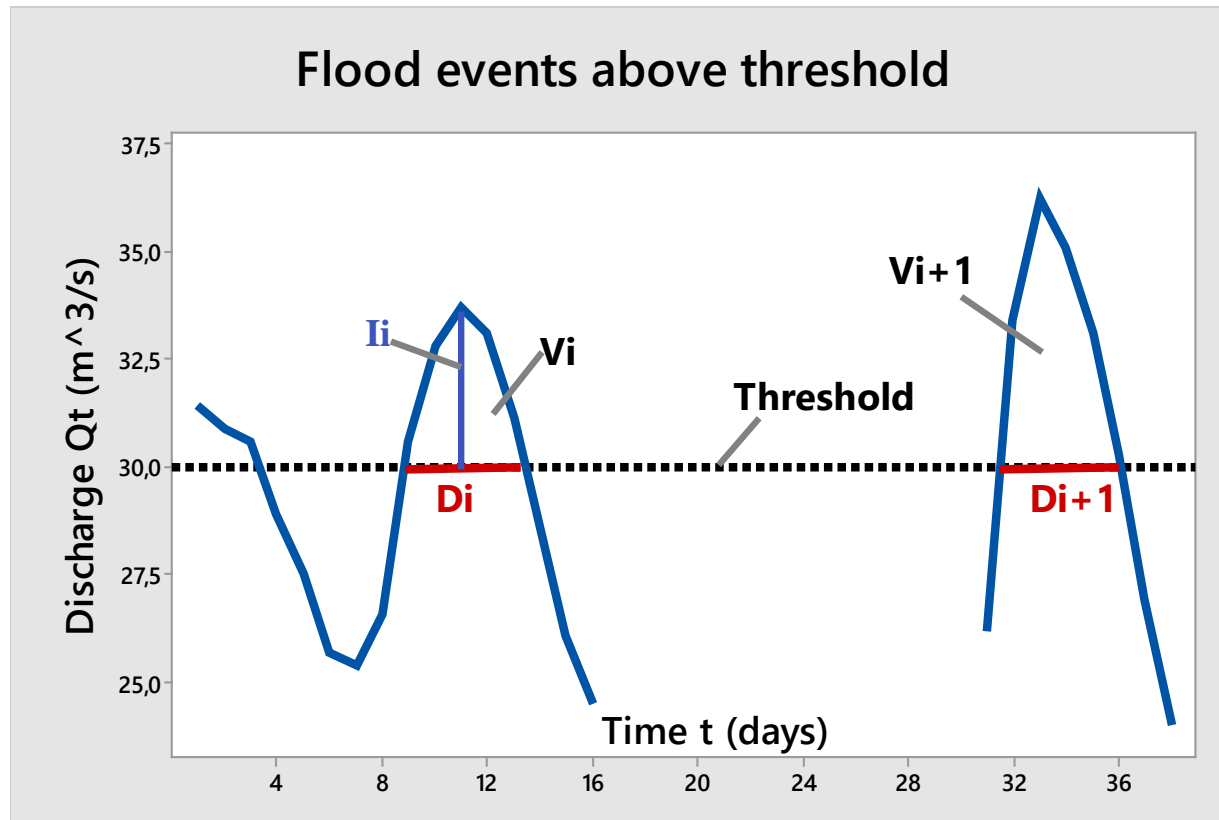

**Non-seasonal flood models do not account for seasonal variability in flood characteristics, so there is a need to identify geographical regions with distinct flood sub-populations.**

# Research Results (continued)

**Hence, from daily streamflow data at a site, we developed means of analyzing flood frequencies and their temporal distribution during the year.**

**This allows, using the peaks over threshold method, to get a seasonal portioning of the year**

# Research Results (continued)

# Research Results (continued)

- **The objective is:**
  - 1) To achieve a seasonal portioning of the year based on the time distribution of flood occurrences
  - 2) To assemble stations similar in flood seasonality into “homogeneous regions based on seasonality”
- **A homogeneous region is characterized by:**
  - The number of significant “seasons”
  - The dates of beginning and end of each season
- **A Mann-Whitney homogeneity test is used to:**

Confirm whether or not seasonal modeling is needed at a site

## Distribution of exceedances during the year

## Seasonality plots

Hydrometric station 01AJ010 (New Brunswick)

## Distribution of exceedances during the year

## Seasonality plots

Hydrometric station 01FB001 (Nova Scotia)

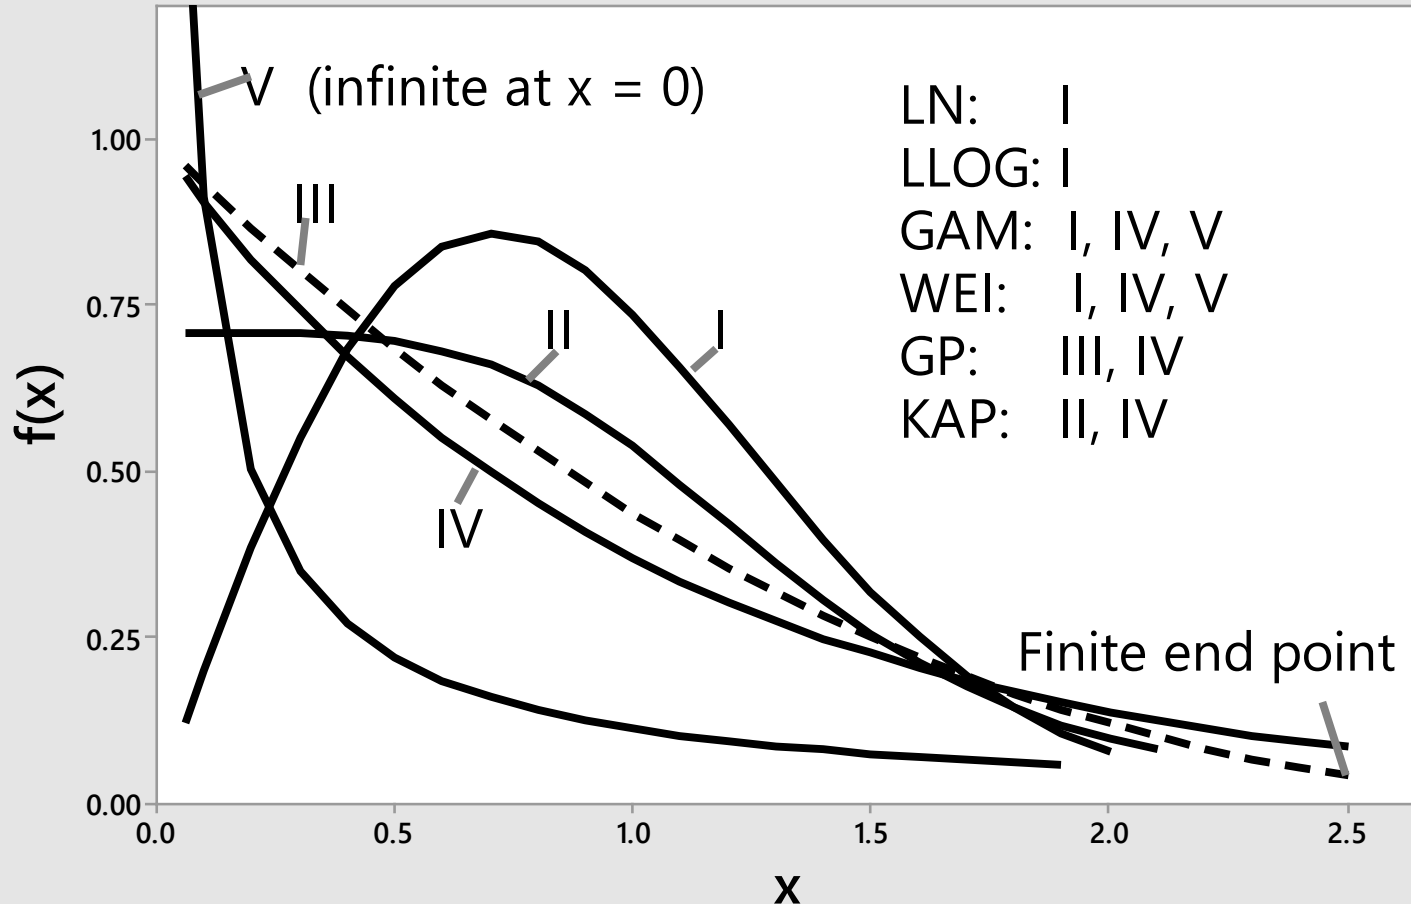

# Research Results (continued)

## 3)

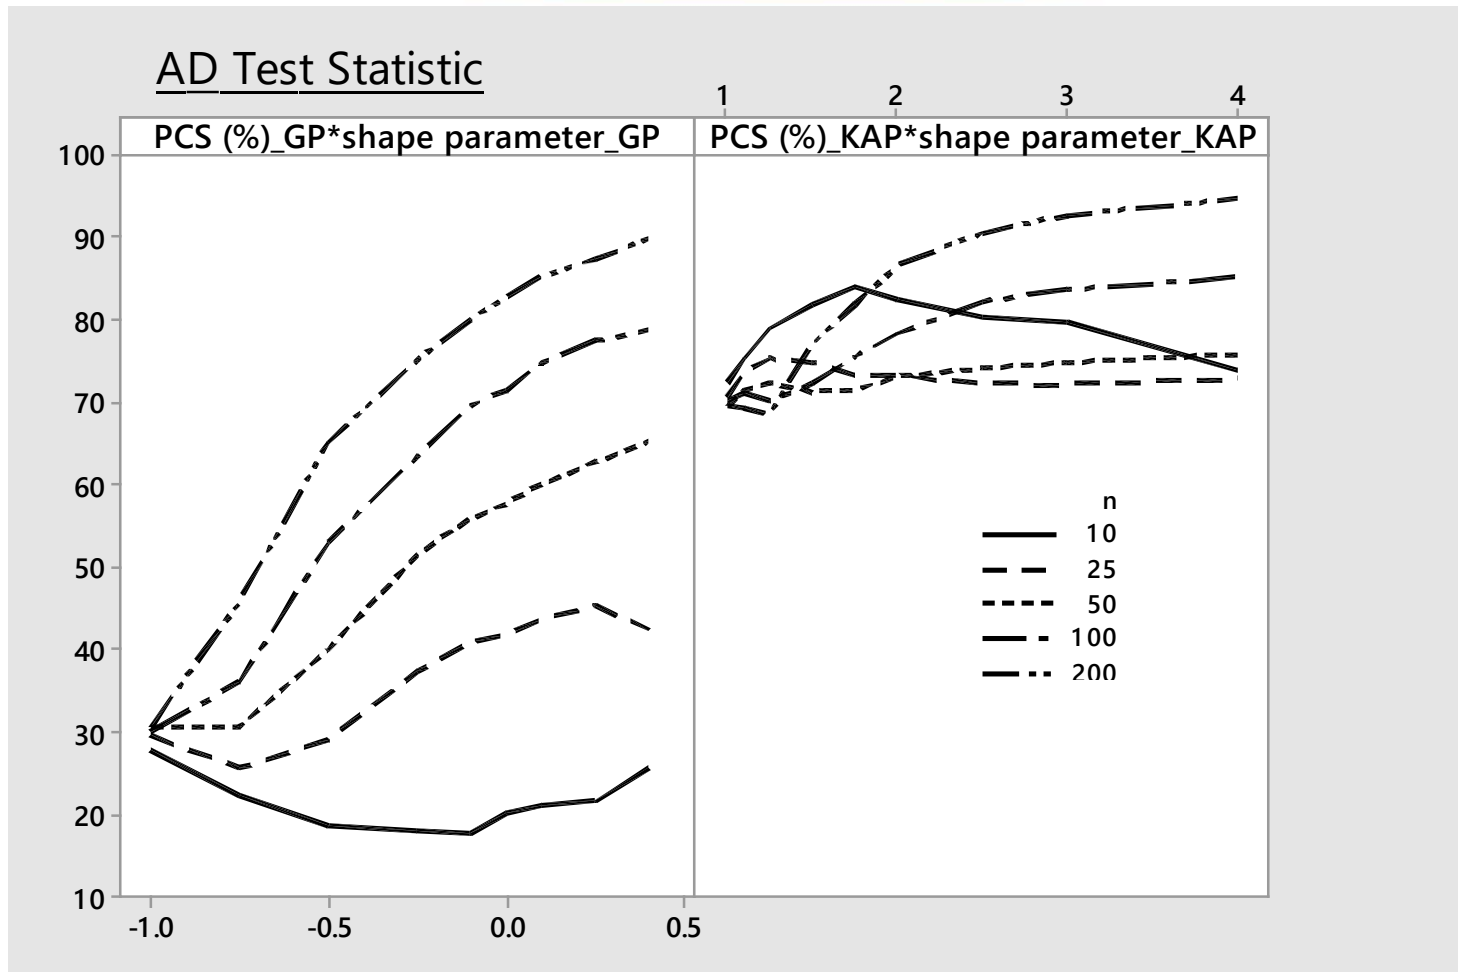

**New results were obtained on the discrimination between statistical distributions for hydrological frequency analysis.**

- GP and KAP models**
- Gumbel and some alternative models**
- Model pairs belonging to the group {GEV, P3, GLO}**

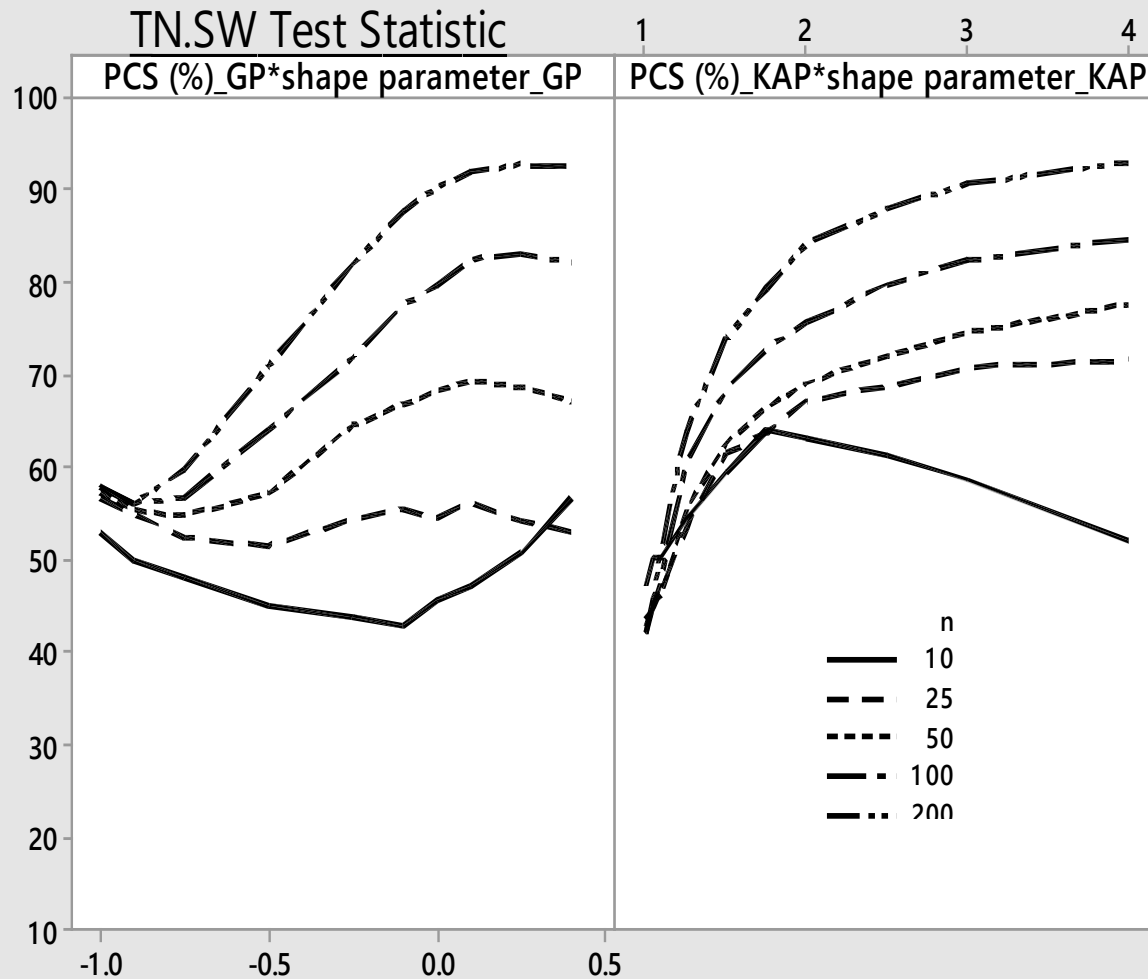

# Example: Discrimination between Gumbel (GEV with shape parameter = 0) and GEV with shape parameter = 0.2

# Example: Discrimination between generalized Pareto and Kappa distributions

# Example (continued)

# Research Results (continued)

4)

**Research is continuing on:**

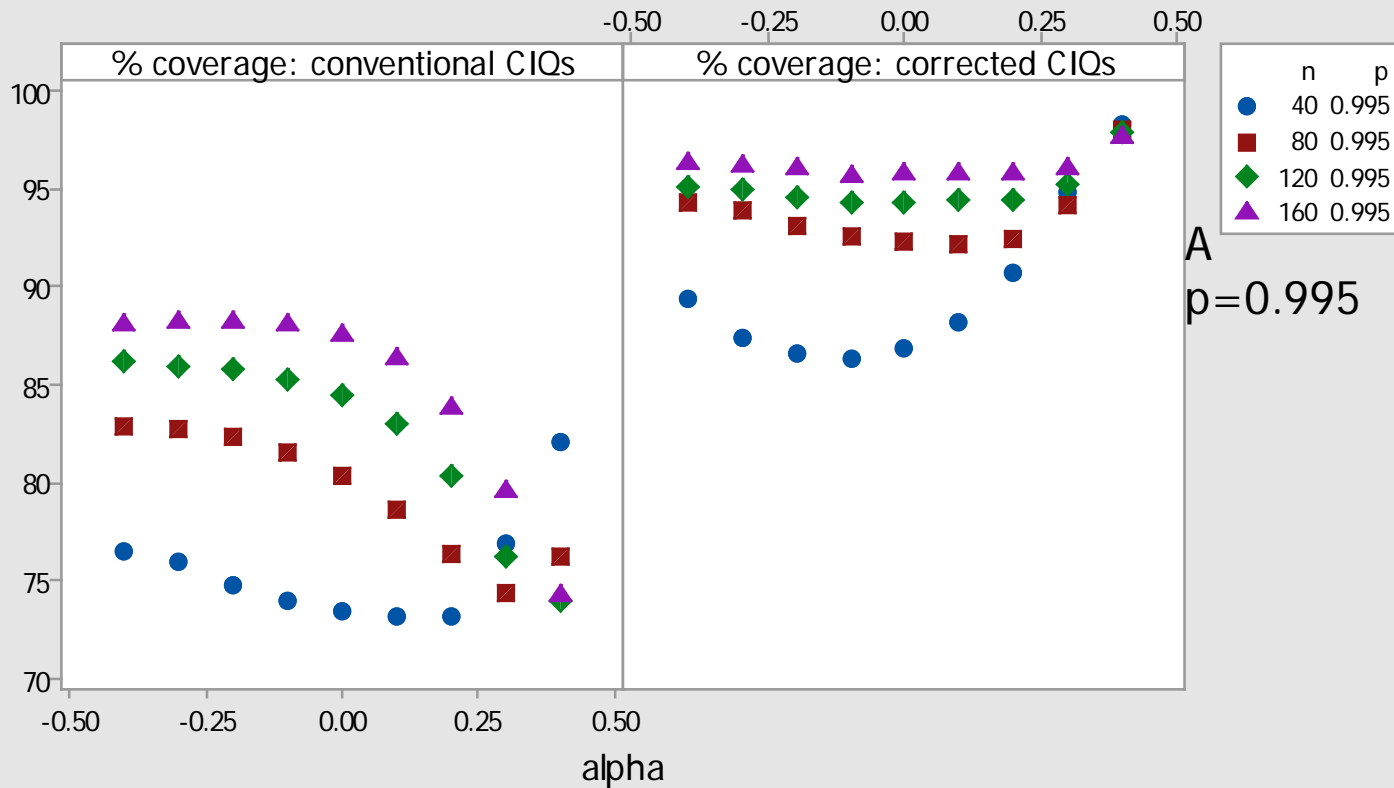

- **Adjusting for small-sample non-normality of design event estimators (extreme distribution quantiles)**

**This allows obtaining:**

- **Improved confidence intervals for quantiles (CIQs)**

# Example: Improved confidence intervals for quantiles

Scatterplot of % coverage: conv, % coverage: corr vs alpha

Results include rows where (n=40 Or n=80 Or n=120 Or n=160) And p=.995.

# Ongoing and short-term research

**Making the research results as user-friendly as possible; specifically results pertaining to:**

- Improved discrimination between distributions**
- Improved confidence intervals for quantiles (CIQs)**

**Thank you!**
